

Proof of Individual Agent Opinion Convergence in a Strongly Connected Influence Graph Using Classic Update Function

Bernardo T. Amorim

March 2020

Definition 1. The *classic update-function*, is defined as:

$$Bel_p^{t+1}(a_i|a_j) = Bel_p^t(a_i) + In(a_j, a_i)(Bel_p^t(a_j) - Bel_p^t(a_i)). \quad (1)$$

Definition 2. While the *overall classic update*, is defined as:

$$Bel_p^{t+1}(a_i) = \frac{1}{|A|} \sum_{a_j \in A} Bel_p^{t+1}(a_i|a_j). \quad (2)$$

Definition 3. We say a influence graph is *strongly connected* if every agent exerts influence on every other agent: $In(a_i, a_j) > 0$, for every i, j .

Definition 4. max_t and min_t are the maximum and minimum belief values in a given instant t , respectively.

To prove our conjecture, let's do some simplifications:

$$\begin{aligned} Bel_p^{t+1}(a_i) &= \frac{1}{|A|} \sum_{a_j \in A} Bel_p^{t+1}(a_i|a_j). \\ &= \frac{1}{|A|} \sum_{a_j \in A} (Bel_p^t(a_i) + In(a_j, a_i)(Bel_p^t(a_j) - Bel_p^t(a_i))) \\ &= Bel_p^t(a_i) + \frac{1}{|A|} \sum_{a_j \in A} In(a_j, a_i)(Bel_p^t(a_j) - Bel_p^t(a_i)) \end{aligned}$$

Since we have a finite number of beliefs and $\forall a_i \in A : Bel_p^t(a_i) \in [0, 1]$, always have a min_t and a max_t . We shall also note that, by the squeeze theorem, individual agent opinion converges to the same value if and only if $\lim_{t \rightarrow \infty} min_t = \lim_{t \rightarrow \infty} max_t$.

Thus, since we want to prove that it always converges, if $min_t = max_t$ we have nothing to prove, so assume $min_t \neq max_t$.

Lemma 1. *In a strongly connected graph and under classic belief update, if $\max_t \neq \min_t$:*

$$\forall a_i \in A : Bel_p^{t+1}(a_i) < \max_t \quad (3)$$

and:

$$\forall a_i \in A : Bel_p^{t+1}(a_i) > \min_t \quad (4)$$

Proof. By definition:

$$Bel_p^{t+1}(a_i) = Bel_p^t(a_i) + \frac{1}{|A|} \sum_{a_j \in A} In(a_j, a_i)(Bel_p^t(a_j) - Bel_p^t(a_i))$$

Now since $\max_t \neq \min_t$, there is at least one $a_j \in A$, such that $Bel_p^t(a_j) < \max_t$, thus replacing all $Bel_p^t(a_j)$ by \max_t , we make the right side strictly greater than the left one:

$$\begin{aligned} Bel_p^{t+1}(a_i) &< Bel_p^t(a_i) + \frac{1}{|A|} \sum_{a_j \in A} In(a_j, a_i)(\max_t - Bel_p^t(a_i)) \\ &< Bel_p^t(a_i) + \frac{1}{|A|} \sum_{a_j \in A} (\max_t - Bel_p^t(a_i)) \\ &< Bel_p^t(a_i) + \frac{|A|}{|A|}(\max_t - Bel_p^t(a_i)) \\ &< Bel_p^t(a_i) + \max_t - Bel_p^t(a_i) \\ Bel_p^{t+1}(a_i) &< \max_t \end{aligned}$$

Since a_i was arbitrary, the lemma is true for all agents. The same reasoning can be used to show the equivalent property for \min_t \square

Corollary 1. *In a strongly connected influence graph and a classic update function, if $\min_t \neq \max_t$, then $\max_{t+1} < \max_t$ and $\min_{t+1} > \min_t$.*

Proof. The result of Lemma 1 tells us that all beliefs in the time $t+1$ are smaller than \max_t , thus, since \max_{t+1} must be one of those elements, $\max_{t+1} < \max_t$. And the same reasoning can be used for \min_t . \square

Corollary 2. $\lim_{t \rightarrow \infty} \max_t = L$ and $\lim_{t \rightarrow \infty} \min_t = M$ for some $L, M \in [0, 1]$.

Proof. Since both \max_t and \min_t are bounded between 0 and 1 by the definition of belief; and Lemma 1 showed us that they are monotonic, according to the monotonic convergence theorem, the limits exist. \square

Definition 5. Let's denote by In_{min} the smallest influence in the influence graph. Keep in mind that $In_{min} > 0$ since we are working with a *strongly connected* influence graph.

Using the same notation we used in Corollary 2, let's call $\lim_{t \rightarrow \infty} \max_t = L$ and $\lim_{t \rightarrow \infty} \min_t = M$.

Lemma 2. $\forall a_i \in A : \max_t - Bel_p^{t+1}(a_i) \geq \epsilon$, with $\epsilon = \frac{In_{min} \cdot (L-M)}{|A|}$.

Proof. To prove this lemma, first we will try to find the biggest $Bel_p^{t+1}(a_i)$ possible. Now let's start with the definition of belief:

$$Bel_p^{t+1}(a_i) = Bel_p^t(a_i) + \frac{1}{|A|} \sum_{a_j \in A} In(a_j, a_i)(Bel_p^t(a_j) - Bel_p^t(a_i))$$

To achieve our goal, in each step we will choose the values in the right side of the equation in a way that maximizes it. Trying to do so will guarantee us that the inequality holds for every $Bel_p^{t+1}(a_i)$ and will lead us to ϵ .

The first thing we will do is separate from the summation the element a_k , which we define as the agent who holds the belief min_t in that arbitrary time step.

$$\begin{aligned} & Bel_p^{t+1}(a_i) \\ = & Bel_p^t(a_i) + \frac{1}{|A|} \sum_{a_j \in A \setminus \{a_k\}} In(a_j, a_i)(Bel_p^t(a_j) - Bel_p^t(a_i)) + \frac{In(a_k, a_i)(Bel_p^t(a_k) - Bel_p^t(a_i))}{|A|} \\ = & Bel_p^t(a_i) + \frac{1}{|A|} \sum_{a_j \in A \setminus \{a_k\}} In(a_j, a_i)(Bel_p^t(a_j) - Bel_p^t(a_i)) + \frac{In(a_k, a_i)(min_t - Bel_p^t(a_i))}{|A|} \end{aligned}$$

Now trying to maximize the rightmost term in the inequality, we shall see that, by the definition of min_t : $min_t - Bel_p^t(a_i) \leq 0$. If $min_t - Bel_p^t(a_i)$ values 0, the influence that multiplies it doesn't make any difference, but if it is different of 0 we want the influence to be as small as possible, which is In_{min} .

$$Bel_p^{t+1}(a_i) \leq Bel_p^t(a_i) + \frac{1}{|A|} \sum_{a_j \in A \setminus \{a_k\}} In(a_j, a_i)(Bel_p^t(a_j) - Bel_p^t(a_i)) + \frac{In_{min} \cdot (min_t - Bel_p^t(a_i))}{|A|}$$

Now it's time to choose the value of $Bel_p^t(a_j)$ for all a_j 's that maximizes the right side. Since this part is always positive, we shall pick the maximum value possible, which is max_t .

$$Bel_p^{t+1}(a_i) \leq Bel_p^t(a_i) + \frac{1}{|A|} \sum_{a_j \in A \setminus \{a_k\}} In(a_j, a_i)(max_t - Bel_p^t(a_i)) + \frac{In_{min} \cdot (min_t - Bel_p^t(a_i))}{|A|}$$

Now looking at the terms inside the summation, since $max_t - Bel_p^t(a_i) \geq 0$, the influence that maximizes it is the biggest one possible, which is 1, thus:

$$\begin{aligned}
Bel_p^{t+1}(a_i) &\leq Bel_p^t(a_i) + \frac{1}{|A|} \sum_{a_j \in A \setminus \{a_k\}} (max_t - Bel_p^t(a_i)) + \frac{In_{min} \cdot (min_t - Bel_p^t(a_i))}{|A|} \\
&\leq Bel_p^t(a_i) + \frac{(|A| - 1)(max_t - Bel_p^t(a_i))}{|A|} + \frac{In_{min} \cdot (min_t - Bel_p^t(a_i))}{|A|} \\
&\leq Bel_p^t(a_i) + \frac{(|A| - 1)(max_t - Bel_p^t(a_i)) + In_{min} \cdot (min_t - Bel_p^t(a_i))}{|A|} \\
&\leq \frac{|A| \cdot Bel_p^t(a_i) + (|A| - 1)(max_t - Bel_p^t(a_i)) + In_{min} \cdot (min_t - Bel_p^t(a_i))}{|A|} \\
&\leq \frac{(|A| - 1)max_t + Bel_p^t(a_i) + In_{min} \cdot (min_t - Bel_p^t(a_i))}{|A|} \\
&\leq \frac{(|A| - 1)max_t + Bel_p^t(a_i)(1 - In_{min}) + In_{min} \cdot min_t}{|A|}
\end{aligned}$$

These manipulations made it clearer which value of $Bel_p^t(a_i)$ we should choose to achieve our goal, and it is $Bel_p^t(a_i) = max_t$.

$$\begin{aligned}
Bel_p^{t+1}(a_i) &\leq \frac{(|A| - 1)max_t + max_t(1 - In_{min}) + In_{min} \cdot min_t}{|A|} \\
&\leq \frac{|A|max_t - In_{min} \cdot max_t + In_{min} \cdot min_t}{|A|} \\
&\leq \frac{|A|max_t + In_{min} \cdot (min_t - max_t)}{|A|} \\
&\leq max_t + \frac{In_{min} \cdot (min_t - max_t)}{|A|}
\end{aligned}$$

Now we shall remember that, since max_t is decreasing and min_t is increasing, our choice to make the right side as big as possible is to plug it's limits, which gives us:

$$\begin{aligned}
Bel_p^{t+1}(a_i) &\leq max_t + \frac{In_{min} \cdot (M - L)}{|A|} \\
Bel_p^{t+1}(a_i) - max_t &\leq \frac{In_{min} \cdot (M - L)}{|A|} \\
max_t - Bel_p^{t+1}(a_i) &\geq \frac{In_{min} \cdot (L - M)}{|A|} \\
max_t - Bel_p^{t+1}(a_i) &\geq \epsilon
\end{aligned}$$

□

Corollary 3. $max_t - max_{t+1} \geq \epsilon$

Proof. Since max_{t+1} must be one of the beliefs in the time $t + 1$ and, according to Lemma 2, all of them are smaller than max_t by at least ϵ , max_{t+1} must also be smaller than max_t by a factor of at least ϵ . □

Theorem 1. $\lim_{t \rightarrow \infty} \max_t = L = \lim_{t \rightarrow \infty} \min_t = M$

Proof. Suppose, by contradiction, that $L \neq M$. Plugging this values into the ϵ formula show us that $\epsilon \neq 0$. Since, according to Lemma 2, \max_{t+1} is smaller than \max_t by a factor of ϵ , we can finally reach to a contradiction and end our proof.

To see this contradiction, let's assume we did $v = \lceil \frac{1}{\epsilon} \rceil + 1$ timesteps after $t = 0$. Since \max diminishes by at least ϵ at each step:

$$\begin{aligned} \max_0 &\geq \max_v + \epsilon \left(\left\lceil \frac{1}{\epsilon} \right\rceil + 1 \right) \\ \max_0 &\geq \max_v + \epsilon.v \\ \max_0 - \epsilon.v &\geq \max_v \end{aligned}$$

But $\epsilon.v > 1$, thus $\max_0 < \epsilon.v$. And this would imply that $\max_v < 0$, which contradicts the definition of belief!

Since assuming that $L \neq M$ led us to a contradiction we can conclude that $L = M$. This result implies that all agents belief converge to the same value, as we wanted to prove. \square
