## March 2020

**Definition 1.** In the classic update-function, is defined as:

$$Bel_p^{t+1}(a_i|a_j) = Bel_p^t(a_i) + In(a_j, a_i)(Bel_p^t(a_j) - Bel_p^t(a_i)).$$
 (1)

**Definition 2.** While the *overall classic update*, is defined as:

$$Bel_p^{t+1}(a_i) = \frac{1}{|A|} \sum_{a_i \in A} Bel_p^{t+1}(a_i|a_j).$$
 (2)

**Definition 3.** We say a influence graph is *strongly connected* if every agent exerts influence on every other agent:  $In(a_i, a_j) > 0$ , for every i, j.

**Definition 4.**  $max_t$  and  $min_t$  are the maximum and minimum belief values in a given instant t, respectively.

To prove our conjecture, let's do some simplifications:

$$Bel_p^{t+1}(a_i) = \frac{1}{|A|} \sum_{a_j \in A} Bel_p^{t+1}(a_i|a_j).$$

$$= \frac{1}{|A|} \sum_{a_j \in A} \left( Bel_p^t(a_i) + In(a_j, a_i) (Bel_p^t(a_j) - Bel_p^t(a_i)) \right)$$

$$= Bel_p^t(a_i) + \frac{1}{|A|} \sum_{a_i \in A} In(a_j, a_i) (Bel_p^t(a_j) - Bel_p^t(a_i))$$

Since belief values are finite, by the well-ordering principle we always have a  $min_t$  and a  $max_t$ . It is easy to see, by the squeeze theorem, that individual agent opinion converges to the same value if and only if  $lim_{t\to\infty}$   $min_t = lim_{t\to\infty}$   $max_t$ .

Thus, since we want to prove that it always converges, if  $min_t = max_t$  we have nothing to prove, so assume  $min_t \neq max_t$ .

**Lemma 1.** In a strongly connected graph and under classic belief update, if  $max_t \neq min_t$ :

$$\forall a_i \in A : Bel_p^{t+1}(a_i) < max_t \tag{3}$$

and:

$$\forall a_i \in A : Bel_p^{t+1}(a_i) > min_t \tag{4}$$

*Proof.* By definition:

$$Bel_p^{t+1}(a_i) = Bel_p^t(a_i) + \frac{1}{|A|} \sum_{a_j \in A} In(a_j, a_i) (Bel_p^t(a_j) - Bel_p^t(a_i))$$

Now since  $max_t \neq min_t$ , there is at least one  $a_j \in A$ , such that  $Bel_p^t(a_j) < max_t$ , thus replacing all  $Bel_p^t(a_j)$  by  $max_t$ , we make the right side strictly greater than the left one:

$$Bel_{p}^{t+1}(a_{i}) < Bel_{p}^{t}(a_{i}) + \frac{1}{|A|} \sum_{a_{j} \in A} In(a_{j}, a_{i}) (max_{t} - Bel_{p}^{t}(a_{i}))$$

$$< Bel_{p}^{t}(a_{i}) + \frac{1}{|A|} \sum_{a_{j} \in A} (max_{t} - Bel_{p}^{t}(a_{i}))$$

$$< Bel_{p}^{t}(a_{i}) + \frac{|A|}{|A|} (max_{t} - Bel_{p}^{t}(a_{i}))$$

$$< Bel_{p}^{t}(a_{i}) + max_{t} - Bel_{p}^{t}(a_{i})$$

$$Bel_{p}^{t+1}(a_{i}) < max_{t}$$

Since  $a_i$  was arbitrary, the lemma is true for all agents. The same reasoning can be used to show the equivalent property for  $min_t$ 

**Corollary 1.** In a strongly connected influence graph and a classic update function, if  $min_t \neq max_t$ , then  $max_{t+1} < max_t$  and  $min_{t+1} > min_t$ .

*Proof.* The result of Lemma 1 tells us that all beliefs in the time t+1 are smaller than  $max_t$ , thus, since  $max_{t+1}$  must be one of those elements,  $max_{t+1} < max_t$ . And the same reasoning can be used for  $min_t$ .

Corollary 2.  $\lim_{t\to\infty} \max_t = L \text{ and } \lim_{t\to\infty} \min_t = M \text{ for some } L, M \in [0,1].$ 

*Proof.* Since both  $max_t$  and  $min_t$  are bounded between 0 and 1 by the definition of belief; and Lemma 1 showed us that they are monotonic, according to the monotonic convergence theorem, the limits exist.

**Definition 5.** Let's denote by  $In_{min}$  the smallest influence in the influence graph. Keep in mind that  $In_{min} > 0$  since we are working with a strongly connected influence graph.

Using the same notation we used in Corollary 2, let's call  $\lim_{t\to\infty} \max_t = L$  and  $\lim_{t\to\infty} \min_t = M$ .

**Lemma 2.** 
$$\forall t, \forall a_i \in A: \max_t - Bel_p^{t+1}(a_i) \geq \epsilon, \text{ with } \epsilon = \frac{In_{min}(L-M)}{|A|}.$$

*Proof.* To prove this lemma, first we will try to find the biggest  $Bel_p^{t+1}(a_i)$  possible. Now let's start with the definition of belief:

$$Bel_p^{t+1}(a_i) = Bel_p^t(a_i) + \frac{1}{|A|} \sum_{a_i \in A} In(a_j, a_i) (Bel_p^t(a_j) - Bel_p^t(a_i))$$

To achieve our goal, in each step we will choose the values in the right side of the equation in a way that maximizes it. Trying to do so will guarantee us that the inequality holds for every  $Bel_p^{t+1}(a_i)$  and will lead us to  $\epsilon$ .

The first thing we will do is separate from the summation the element  $a_k$ , which we define as the agent who holds the belief  $min_t$  in that arbitrary time step.

$$Bel_{p}^{t+1}(a_{i})$$

$$=Bel_{p}^{t}(a_{i}) + \frac{1}{|A|} \sum_{a_{j} \in A \setminus \{a_{k}\}} In(a_{j}, a_{i})(Bel_{p}^{t}(a_{j}) - Bel_{p}^{t}(a_{i})) + \frac{In(a_{k}, a_{i})(Bel_{p}^{t}(a_{k}) - Bel_{p}^{t}(a_{i}))}{|A|}$$

$$=Bel_{p}^{t}(a_{i}) + \frac{1}{|A|} \sum_{a_{j} \in A \setminus \{a_{k}\}} In(a_{j}, a_{i})(Bel_{p}^{t}(a_{j}) - Bel_{p}^{t}(a_{i})) + \frac{In(a_{k}, a_{i})(min_{t} - Bel_{p}^{t}(a_{i}))}{|A|}$$

Now trying to maximize the rightmost term in the inequality, we shall see that, by the definition of  $min_t$ :  $min_t - Bel_p^t(a_i) \leq 0$ . If  $min_t - Bel_p^t(a_i)$  values 0, the influence that multiplies it doesn't make any difference, but if it is different of 0 we want the influence to be as small as possible, which is  $In_{min}$ .

$$Bel_p^{t+1}(a_i) \le Bel_p^t(a_i) + \frac{1}{|A|} \sum_{a_j \in A \setminus \{a_k\}} In(a_j, a_i) (Bel_p^t(a_j) - Bel_p^t(a_i)) + \frac{In_{min}.(min_t - Bel_p^t(a_i))}{|A|}$$

Now it's time to choose the value of  $Bel_p^t(a_j)$  for all  $a_j$ 's that maximizes the right side. Since this part is always positive, we shall pick the maximum value possible, which is  $max_t$ .

$$Bel_p^{t+1}(a_i) \le Bel_p^t(a_i) + \frac{1}{|A|} \sum_{a_j \in A \setminus \{a_k\}} In(a_j, a_i) (max_t - Bel_p^t(a_i)) + \frac{In_{min}.(min_t - Bel_p^t(a_i))}{|A|}$$

Now looking at the terms inside the summation, since  $max_t - Bel_p^t(a_i) \geq 0$ , the influence that maximizes it is the biggest one possible, which is 1, thus:  $\forall a_i, a_j \in A \setminus \{a_k\}$ :  $In(a_j, a_i) = 1$ .

$$\begin{split} Bel_{p}^{t+1}(a_{i}) &\leq Bel_{p}^{t}(a_{i}) + \frac{1}{|A|} \sum_{a_{j} \in A \setminus \{a_{k}\}} (max_{t} - Bel_{p}^{t}(a_{i})) + \frac{In_{min}.(min_{t} - Bel_{p}^{t}(a_{i}))}{|A|} \\ &\leq Bel_{p}^{t}(a_{i}) + \frac{(|A| - 1)(max_{t} - Bel_{p}^{t}(a_{i}))}{|A|} + \frac{In_{min}.(min_{t} - Bel_{p}^{t}(a_{i}))}{|A|} \\ &\leq Bel_{p}^{t}(a_{i}) + \frac{(|A| - 1)(max_{t} - Bel_{p}^{t}(a_{i})) + In_{min}.(min_{t} - Bel_{p}^{t}(a_{i}))}{|A|} \\ &\leq \frac{|A| \ Bel_{p}^{t}(a_{i}) + (|A| - 1)(max_{t} - Bel_{p}^{t}(a_{i})) + In_{min}.(min_{t} - Bel_{p}^{t}(a_{i}))}{|A|} \\ &\leq \frac{(|A| - 1) \ max_{t} - Bel_{p}^{t}(a_{i}) + In_{min}.(min_{t} - Bel_{p}^{t}(a_{i}))}{|A|} \\ &\leq \frac{(|A| - 1) \ max_{t} + Bel_{p}^{t}(a_{i})(1 - In_{min}) + In_{min}.min_{t}}{|A|} \end{split}$$

These manipulations made it clear which value of  $Bel_p^t(a_i)$  we should choose to achieve our goal, and it is  $Bel_p^t(a_i) = max_t$ .

$$Bel_{p}^{t+1}(a_{i}) \leq \frac{(|A|-1) \max_{t} + \max_{t} (1 - In_{min}) + In_{min}.min_{t}}{|A|}$$

$$\leq \frac{|A| \max_{t} - In_{min}.max_{t} + In_{min}.min_{t}}{|A|}$$

$$\leq \frac{|A| \max_{t} + In_{min}.(min_{t} - max_{t})}{|A|}$$

$$\leq \max_{t} + \frac{In_{min}.(min_{t} - max_{t})}{|A|}$$

Now we shall remember that, since  $max_t$  is decreasing and  $min_t$  is increasing, our choice to make the right side as big as possible is to plug it's limits, which gives us:

$$Bel_p^{t+1}(a_i) \le max_t + \frac{In_{min}.(M-L)}{|A|}$$

$$Bel_p^{t+1}(a_i) - max_t \le \frac{In_{min}.(M-L)}{|A|}$$

$$max_t - Bel_p^{t+1}(a_i) \ge \frac{In_{min}.(L-M)}{|A|}$$

$$max_t - Bel_p^{t+1}(a_i) \ge \epsilon$$

Corollary 3.  $max_t - max_{t+1} \ge \epsilon$ 

*Proof.* Since  $max_{t+1}$  must be one of the beliefs in the time t+1 and, according to Lemma 2, all of them are smaller than  $max_t$  by at least  $\epsilon$ ,  $max_{t+1}$  must also be smaller than  $max_t$  by a factor of at least  $\epsilon$ .

Theorem 1.  $\lim_{t\to\infty} max_t = L = \lim_{t\to\infty} min_t = M$ 

*Proof.* Suppose, by contradiction, that  $L \neq M$ . Plugging this values into the  $\epsilon$  formula show us that  $\epsilon \neq 0$ . Since, according to Lemma 2,  $max_{t+1}$  is smaller than  $max_t$  by a factor of  $\epsilon$ . All that being said, we can finally reach to a contradiction and end our proof.

To see this contradiction, let's assume we did  $v = \lceil \frac{1}{\epsilon} \rceil + 1$  timesteps after some t = 0. Since max diminishes by at least  $\epsilon$  at each step:

$$max_0 \ge max_v + \epsilon \left( \left\lceil \frac{1}{\epsilon} \right\rceil + 1 \right)$$
$$max_0 \ge max_v + \epsilon.v$$
$$max_0 - \epsilon.v \ge max_v$$

But  $\epsilon v > 1$ , thus  $\max_0 < \epsilon v$ . And this would imply that  $\max_v < 0$ , which contradicts the definition of belief!

Since assuming that  $L \neq M$  led us to a contradiction we can conclude that L = M. This result implies that all agents belief converge to the same value, as we wanted to prove.
